UAW-GM Cohort Study

With additional model terms; exposure lagged 21 years

November 12, 2019

Introduction

In previous survival analyses, hazard ratios associated with exposure to the three metalworking fluid types were estimated simultaneously in the same Cox proportional hazards model. There was a concern that those estimates may have been biased or misleading, as those models assumed independent covariate (statistical) effects e.g. that the effect of exposure to straight metalworking fluids was constant across levels of exposure to other metalworking fluid types. One way we attempted to address this concern was to fit independent models for each exposure-outcome pair of interest with one additional term to capture changes in the log-hazard associated with the combination of zero exposure to one metalworking fluid type and nonzero exposure to some other metalworking fluid type.

Model

Let $\boldsymbol{W}(t)$ represent the vector of potential confounders at time t. Let X_{St}, $X_{\mathrm{So}}(t)$, and $X_{\mathrm{Sy}}(t)$ represent cumulative exposure to straight, soluble, and synthetic metalworking fluids, respectively at time t. If we were interested in straight metalworking fluids, then the log hazard for the outcome could be modeled:

$$
\begin{aligned}
\log\left[h\left(t \mid \boldsymbol{W}(t) = \boldsymbol{w}(t), \boldsymbol{X}(t) = \boldsymbol{x}(t), \hat{\boldsymbol{\beta}}\right)\right] = {} & \log\left[h_0(t)\right] \\
& + \hat{\beta}_1 \mathbb{1}\left[x_{\mathrm{St}}(t) \in (0, \mathrm{St}_{\mathrm{low}}]\right] \\
& + \hat{\beta}_2 \mathbb{1}\left[x_{\mathrm{St}}(t) \in (\mathrm{St}_{\mathrm{low}}, \mathrm{St}_{\mathrm{mid}}]\right] \\
& + \hat{\beta}_3 \mathbb{1}\left[x_{\mathrm{St}}(t) \in (\mathrm{St}_{\mathrm{mid}}, \mathrm{St}_{\mathrm{high}}]\right] \\
& + \hat{\beta}_4 \mathbb{1}\left[x_{\mathrm{So}}(t) \in (0, \mathrm{So}_{\mathrm{low}}]\right] \\
& + \hat{\beta}_5 \mathbb{1}\left[x_{\mathrm{So}}(t) \in (\mathrm{So}_{\mathrm{low}}, \mathrm{So}_{\mathrm{mid}}]\right] \\
& + \hat{\beta}_6 \mathbb{1}\left[x_{\mathrm{So}}(t) \in (\mathrm{So}_{\mathrm{mid}}, \mathrm{So}_{\mathrm{high}}]\right] \\
& + \hat{\beta}_7 \mathbb{1}\left[x_{\mathrm{Sy}}(t) \in (0, \mathrm{Sy}_{\mathrm{low}}]\right] \\
& + \hat{\beta}_8 \mathbb{1}\left[x_{\mathrm{Sy}}(t) \in (\mathrm{Sy}_{\mathrm{low}}, \mathrm{Sy}_{\mathrm{mid}}]\right] \\
& + \hat{\beta}_9 \mathbb{1}\left[x_{\mathrm{Sy}}(t) \in (\mathrm{Sy}_{\mathrm{mid}}, \mathrm{Sy}_{\mathrm{high}}]\right] \\
& + \hat{\beta}_{10} \mathbb{1}\left[x_{\mathrm{St}}(t) = 0\right] \mathbb{1}\left[x_{\mathrm{So}}(t) + x_{\mathrm{Sy}}(t) > 0\right] \\
& + \hat{\beta}_{11} w_1(t) + \hat{\beta}_{12} w_2(t) + \hat{\beta}_{13} w_3(t) + \cdots
\end{aligned}
$$

where $\mathrm{St}_{\mathrm{low}}$, $\mathrm{So}_{\mathrm{low}}$, and $\mathrm{Sy}_{\mathrm{low}}$ represent the upper boundaries of low exposure to the three types of metalworking fluids among cases at time of death, respectively; $\mathrm{St}_{\mathrm{mid}}$, $\mathrm{So}_{\mathrm{mid}}$, and $\mathrm{Sy}_{\mathrm{mid}}$ represent the upper boundaries of moderate exposure among cases at time of death; and $\mathrm{St}_{\mathrm{high}}$, $\mathrm{So}_{\mathrm{high}}$, and $\mathrm{Sy}_{\mathrm{high}}$ represent maximum exposure among cases at time of death. If we were interested in exposure to soluble metalworking fluids, we would replace the 10th covariate with $\mathbb{1}\left[x_{\mathrm{So}}(t) = 0\right] \mathbb{1}\left[x_{\mathrm{St}}(t) + x_{\mathrm{Sy}}(t) > 0\right]$. For synthetic, we would replace with $\mathbb{1}\left[x_{\mathrm{Sy}}(t) = 0\right] \mathbb{1}\left[x_{\mathrm{St}}(t) + x_{\mathrm{So}}(t) > 0\right]$. Note that if all three terms were included simultaneously, we would have a rank-deficient model matrix.

Results

Table 1: Cox model estimates of the hazard ratio for selected cancer outcomes associated with exposure to **straight** metalworking fluids, controlling for other fluid types, calendar year, calendar year of hire, age, race, sex, and plant.

		Number of cases	HR	p	95% CI
